## Exercise 4 November 4, 2019

Submission online until Tuesday, 12.11.2019, 11:55 am

Objective: In this exercise you will write a program to read white points in the floor with the RGBD camera of the car and use those points to compute the location and orientation of the camera in the space. In order to achieve this objective, functions from the OpenCV library must be used.

#### **Assignment 4-1: Field Preparation**

Play the provided bagfile in a loop:

rosbag play -l calibration.bag

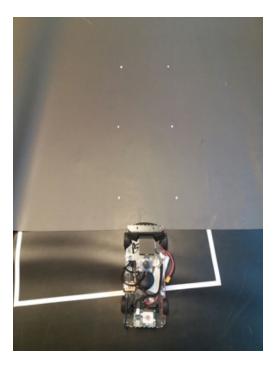

Figure 1: Prepared field

## Assignment 4-2: Camera parameters (1 Point)

Take a look at the definition of the sensor\_msgs/CameraInfo message type:

http://docs.ros.org/melodic/api/sensor\_msgs/html/msg/CameraInfo.html

Extract the intrinsic parameters  $f_x, f_y, c_x, c_y$  and distortion coefficients  $k_1, k_2, t_1, t_2, k_3$  from the /sensors/camera/infra1/camera\_info topic.

#### Assignment 4-3: Binary Image (2 Point)

Use the threshold function from OpenCV to turn your gray image into binary image. Play with the intervals until you find the best threshold where the white marks are separated nicely. Draw black rectangles over the remaining white pixels in the binary image that are not the field markings. Publish your image. (see Fig. 2b)

(a) Greyscale image

(b) Binary image

Figure 2: Images

### Assignment 4-4: Find white pixels (2 Points)

Now, divide the thresholded image into 6 regions so that every region has one marker. For every region extract all the white pixels and calculate the average position to get the center of the marking. Remember that the coordinates of the image are as follows:

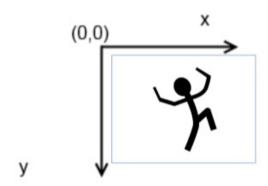

Figure 3: OpenCV image coordinates

# Assignment 4-5: Compute the extrinsic parameters (3 Points)

Here you will have to use solvePnP function of OpenCV to calculate the extrinsic camera parameters using the points obtained in the last part. Take a look at the documentation at:

https://docs.opencv.org/2.4/modules/calib3d/doc/camera\_calibration\_and\_3d\_reconstruction.html

Define a 3x3 numpy array for the intrinsic parameters and use the values from task 1. Create a 5x1 numpy array for the distortion parameters retrieved from task 1.

Use the marker centers from the previous task and map them to the real world coordinates. The real world coordinates for the images are as follows, with the world origin being in the car's base\_link frame which is the center of the rear axle:

```
\begin{array}{lll} \text{bottom left} & (0.5,\,0.2) \\ \text{bottom right} & (0.5,\,-0.2) \\ \text{middle left} & (0.8,\,0.2) \\ \text{middle right} & (0.8,\,-0.2) \\ \text{top left} & (1.1,\,0.2) \\ \text{top right} & (1.1,\,-0.2) \end{array}
```

Note, the order of the image points and the real world coordinates passed to solvePnP has to match.

Print your results in a terminal.

## Assignment 4-6: Finding the camera pose (2 Points)

From the previous task you got the rvec and tvec parameters. Use the OpenCV function Rodrigues to convert rvec into a rotation matrix. What is the homogeneous 4x4 transformation matrix? In which frame is the resulting transformation? What is its inverse?
